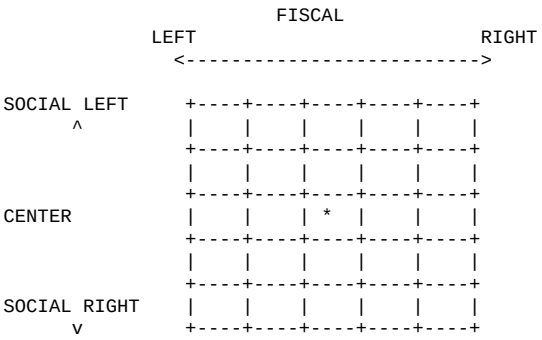
LIP

Political Measurement, Community Verification, Debate & Collective Action

LIP is a political-spectrum social network built around three activities: **Measure - Verify - Act.** AI proposes measurements, the community inspects evidence and challenges individual points, and the system uses those verified measurements to map candidates, media, organizations, economic relationships, debates, and boycotts.

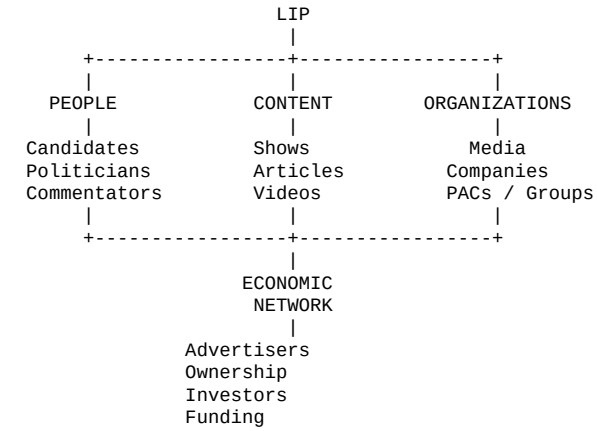
Core Spectrum

LIP uses two independent dimensions. Fiscal position runs left-to-right; social position runs top-to-bottom. Each axis contains five positions: Left, Center Left, Center, Center Right, Right. Together they form a 5 x 5 political position matrix, while the four larger quadrants remain an intuitive visual metaphor.



What LIP Measures

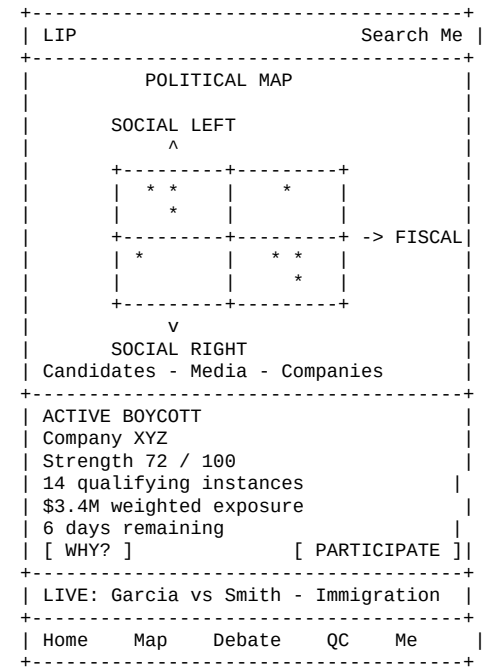
The ontology is broader than people. LIP can measure candidates, politicians, commentators, shows, articles, videos, media organizations, companies, PACs/groups, advertisers, owners, investors, and funding relationships. Everything ultimately resolves to evidence and individual measurements.



Example evidence chain: **CNN -> The Whole Story -> Episode -> Issue / Statement / Treatment -> AI observations -> Evidence -> Scored points -> Community QC.** LIP should explain why something receives a position rather than merely assign a label.

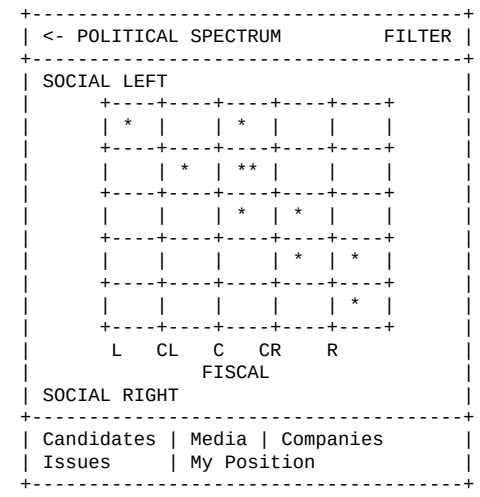
1. Home

The home screen answers three immediate questions: Where is everything on the political map? What is changing? What is the community doing about it? The political map and current boycott are the dominant objects.



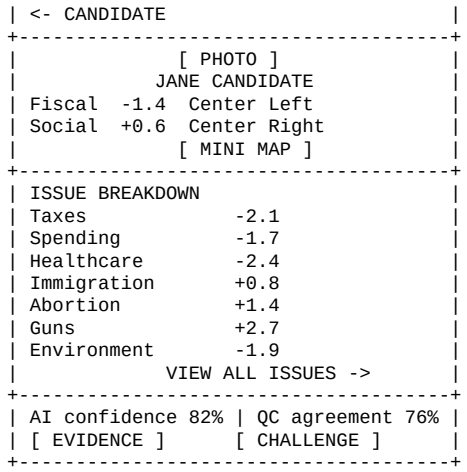
2. Spectrum

Tapping the map opens the 5 x 5 measurement system. Candidates, media, companies, issues, and the user's own position can be filtered and plotted on the same coordinate system.



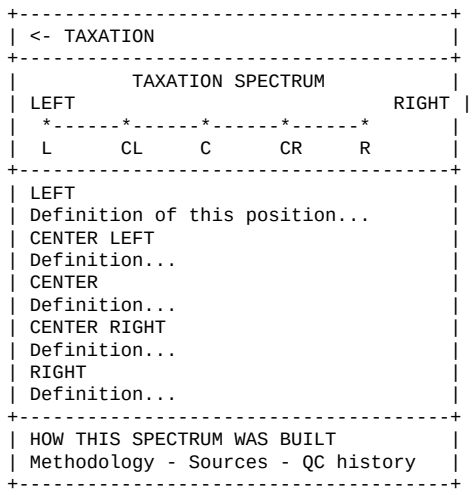
3. Candidate

A candidate is not assigned one mysterious LIP score. The position is built upward from topic measurements, evidence, AI confidence, and community QC.



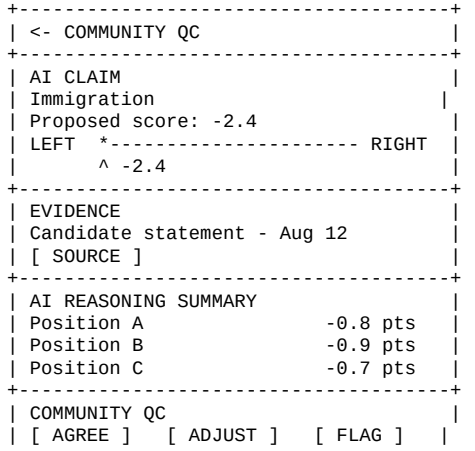
4. Issue Spectrum

Every fiscal and social topic receives its own published spectrum. The definitions of Left, Center Left, Center, Center Right, and Right become part of the measurement instrument itself.



5. AI -> Community QC

Community quality control should operate at the measurement level, not only as a thumbs-up/down reaction to a final conclusion. Members can agree, propose an adjustment, or flag evidence/methodology.



```
| Community result: -2.2              |
| Confidence: 81%                     |
+-------------------------------------+
```

6. Organizations and the Apply-Up Model

Measurements can propagate through relationships, but the political score should not simply be copied upward. Instead, LIP should calculate an **attribution weight**. This distinguishes a measured political position from responsibility, funding exposure, ownership exposure, or sponsorship exposure.

```
Political Instance
       |
       v
   Episode / Story
       |
       v
      Show
       |
       v
    Network
       |
       +----------------+
       v                v
  Advertisers        Ownership
       |                |
       v                v
 Advertiser Co.      Parent Co.
                        |
                        v
                     Investors
```

For example, an instance scored -3.2 with 92% confidence may pass fully to the program, partially to the network according to editorial/control weight, partially to an advertiser according to sponsorship exposure, and only fractionally to an investor according to ownership amount. This preserves relationships without asserting that every connected party holds the same political position.

7. Boycott

A boycott is an output of measured and verified conditions rather than simply a petition. Its strength and duration can be calculated from qualifying instances, severity, community confidence, recency, advertising exposure, investor weighting, and other defined factors.

```
+-------------------------------------+
| <- BOYCOTT                          |
+-------------------------------------+
|             COMPANY XYZ             |
| BOYCOTT STRENGTH                    |
|               72 / 100              |
|                 HIGH                |
+-------------------------------------+
| WHY NOW?                            |
| Qualifying instances            14  |
| Severity                         68 |
| Community confidence            84% |
| Advertising exposure          $3.4M |
| Investor weighting                61 |
| Recency                           92 |
| CALCULATED DURATION           7 DAYS|
+-------------------------------------+
| Company -> Network -> Program ->    |
| Events        [ EXPLORE CHAIN ]     |
+-------------------------------------+
| 12,481 participating                |
|          [ JOIN BOYCOTT ]           |
+-------------------------------------+
```

Measurement, community QC, and collective action should remain visibly separate. Inspecting or agreeing with an underlying measurement should not automatically imply endorsement of a boycott.

8. Live Debate / Knockout

Gamification centers on live debate, knockout rounds, referees, rankings, and issue expertise. Multiple reputation systems are better than a single follower count: debater rating, referee rating, QC accuracy, evidence contribution, and issue expertise.

```
+--------------------------------------+
| LIVE                          12.4K  |
+--------------------------------------+
|             IMMIGRATION              |
| PLAYER A                 PLAYER B    |
|   1842                     1791      |
|            ROUND 3 OF 5              |
|               01:42                  |
|        [ LIVE VIDEO / AUDIO ]        |
+--------------------------------------+
| ARGUMENT                             |
| Current proposition...               |
+--------------------------------------+
| REFEREES                             |
| Evidence          8.4                |
| Relevance         9.1                |
| Accuracy          8.6                |
| Community decision pending...        |
+--------------------------------------+
| Rankings                 Challenge   |
+--------------------------------------+
```

9. Polling

LIP should explicitly distinguish **community sentiment**, **representative polling**, and **election forecasting**. While samples are small, self-selected, or demographically biased, the interface should not visually imply that LIP participation predicts an actual election.

```
LIP COMMUNITY

Candidate A       57%
Candidate B       43%

Participants: 4,821

NOT AN ELECTION POLL

This represents participating LIP users.
The sample has not been demonstrated to
represent the voting population.

Known sample differences:
Age - Geography - Party - Engagement

Recommended Next Design Pass

The spectrum is the visualization layer; underneath it, LIP is a political measurement graph connecting evidence -> issues -> people/content -> organizations -> economic relationships. Before adding many more screens, define the ontology and scoring engine around seven core concepts: **Object -> Instance -> Evidence -> Measurement -> QC -> Attribution -> Action.**

If those objects are clean, candidates, media programs, episodes, advertisers, investors, debates, and boycotts can all share the same underlying architecture.
